1. Modify the dataset by adding your own custom-generated story, paragraph, or personal content to the document.
2. Preprocess the text data by removing punctuation marks and unnecessary symbols from the documents before tokenization and training.
3. Add separate training and testing data loaders. Train the model using the training dataset and evaluate it on the testing dataset.
4. Calculate and compare the accuracy for both the training and testing datasets. Analyze whether the model is suffering from overfitting or not.
5. If overfitting is observed, apply suitable deep learning techniques discussed in the course, such as dropout, regularization, or early stopping, to reduce it.
6. Improve the overall model performance by reducing the training loss and increasing the prediction accuracy through better preprocessing, architecture tuning, hyperparameter adjustment, or optimization techniques.

Extra: Apply sequence padding in the question answering system so that all input sequences have equal length, then train the complete model using the padded dataset.
